Variables, Expressions, and Statements

Topic# 2

Making Friends with Python

Mrinal Chakraborty

✓ **Programing**: SAS, R-Server, TensorFlow and Scala
✓ **Big-Data:** Cloudera Hadoop certification and Spark Ecosystem
✓ **Machine learning:** Logistic Regression, Neural Networks, Support vector machines, XGBoost, Classification and Association rules
✓ **Allied Analytics skills:** Visualisation, Marketing & Web analytics
✓ **Certifications:** PMP, Certified Scrum Master & Certified in Business analytics from **Indian School of Business** http://www.isb.edu/cba/

Constants

- Fixed values such as numbers, letters, and strings are called "constants" because their value does not change

- Numeric constants are as you expect

- String constants use single quotes (') or double quotes (")

```
>>> print 123
123
>>> print 98.6
98.6
>>> print 'Hello world'
Hello world
```

Variables

- A variable is a named place in the memory where a programmer can store data and later retrieve the data using the variable "name"

- Programmers get to choose the names of the variables

- You can change the contents of a variable in a later statement

```
x = 12.2
y = 14
```

x | 12.2 |

y | 14 |

Variables

- A variable is a named place in the memory where a programmer can store data and later retrieve the data using the variable "name"

- Programmers get to choose the names of the variables

- You can change the contents of a variable in a later statement

```
x = 12.2
y = 14
x = 100
```

x | ~~12.2~~ 100 |

y | 14 |

Python Variable Name Rules

Microsoft

1. Must start with a letter or underscore _

2. Must consist of letters and numbers and underscores

3. Case Sensitive

- Good: spam   eggs   spam23   _speed
- Bad: 23spam   #sign var.12
- Different: spam   Spam   SPAM

Reserved Words

Microsoft

- You cannot use reserved words as variable names / identifiers

and del for is raise assert elif
from   lambda return break   else
global not try class except if or
while continue exec import pass
yield def finally in print as with

Sentences or Lines

Microsoft

```
x = 2
```
———— Assignment statement
```
x = x + 2
```
———— Assignment with expression
```
print x
```
———— Print statement
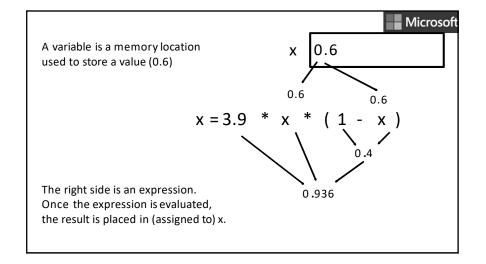

Variable   Operator   Constant   Reserved Word

Assignment Statements

Microsoft

• We assign a value to a variable using the assignment statement (=)

• An assignment statement consists of an expression on the right-hand side and a variable to store the result

```
x = 3.9 * x * ( 1 - x )
```

Slide 1 (left):

A variable is a memory location used to store a value (0.6)

x 0.6

0.6   0.6

x = 3.9 * x * (1 - x)

0.4

0.936

The right side is an expression. Once the expression is evaluated, the result is placed in (assigned to) x.

Microsoft

Slide 2 (right):

A variable is a memory location used to store a value. The value stored in a variable can be updated by replacing the old value (0.6) with a new value (0.93).

x 0.6 0.93

x = 3.9 * x * (1 - x)

0.93

The right side is an expression. Once the expression is evaluated, the result is placed in (assigned to) the variable on the left side (i.e., x).

Microsoft

5

Numeric Expressions

- Because of the lack of mathematical symbols on computer keyboards - we use "computer-speak" to express the classic math operations

- Asterisk is multiplication

- Exponentiation (raise to a power) looks different from in math.

Operator	Operation
+	Addition
-	Subtraction
*	Multiplication
/	Division
**	Power
%	Remainder

Numeric Expressions

```
>>> xx = 2
>>> xx = xx + 2
>>> print xx
4
>>> yy = 440 * 12
>>> print yy
5280
>>> zz = yy / 1000
>>> print zz
5
```

```
>>> jj = 23
>>> kk = jj % 5
>>> print kk
3
>>> print 4 ** 3
64
```

```
      4 R 3
   ┌───────
5  │ 23
     20
     ──
      3
```

Operator	Operation
+	Addition
-	Subtraction
*	Multiplication
/	Division
**	Power
%	Remainder

Order of Evaluation

- When we string operators together - Python must know which one to do first

- This is called "operator precedence"

- Which operator "takes precedence" over the others?

$$x = 1 + 2 * 3 - 4 / 5 ** 6$$

Operator Precedence Rules

Highest precedence rule to lowest precedence rule:

> Parenthesis are always respected

> Exponentiation (raise to a power)

> Multiplication, Division, and Remainder

> Addition and Subtraction

> Left to right

Parenthesis
Power
Multiplication
Addition
Left to Right

Slide 1

```
>>> x = 1 + 2 ** 3 / 4 * 5
>>> print x
11
>>>
```

Parenthesis
Power
Multiplication
Addition
Left to Right

$1+2**3 / 4*5$

$1+8 / 4*5$

$1+2*5$

$1+10$

11

Slide 2

Operator Precedence

Parenthesis
Power
Multiplication
Addition
Left to Right

- Remember the rules top to bottom

- When writing code - use parenthesis

- When writing code - keep mathematical expressions simple enough that they are easy to understand

- Break long series of mathematical operations up to make them more clear

Exam Question: x = 1+ 2 * 3 - 4 / 5

Python Integer Division is Weird!

Microsoft

- Integer division truncates

- Floating point division produces floating point numbers

```
>>> print 10 / 2
5
>>> print 9 / 2
4
>>> print 99 / 100
0
>>> print 10.0 / 2.0
5.0
>>> print 99.0 / 100.0
0.99
```

This changes in Python 3.0

Mixing Integer and Floating

Microsoft

- When you perform an operation where one operand is an integer and the other operand is a floating point, the result is a floating point

- The integer is converted to a floating point before the operation

```
>>> print 99 / 100
0
>>> print 99 / 100.0
0.99
>>> print 99.0 / 100
0.99
>>> print 1 + 2 * 3 / 4.0 - 5
-2.5
>>>
```

What does "Type" Mean?

- In Python variables, literals and constants have a "type"

- Python knows the difference between an integer number and a string

- For example "+" means "addition" if something is a number and "concatenate" if something is a string

```
>>> ddd = 1 + 4
>>> print ddd
5
>>> eee = 'hello ' + 'there'
>>> print eee
hello there
```

concatenate = put together

Type Matters

- Python knows what "type" everything is

- Some operations are prohibited

- You cannot "add 1" to a string

- We can ask Python what type something is by using the type() function

```
>>> eee = 'hello ' + 'there'
>>> eee = eee + 1
Traceback (most recent call last):
  File "<stdin>", line 1, in
<module>
TypeError: cannot concatenate
'str' and 'int' objects
>>> type(eee)
<type 'str'>
>>> type('hello')
<type 'str'>
>>> type(1)
<type 'int'>
>>>
```

Several Types of Numbers

- Numbers have two main types

  > Integers are whole numbers:
    -14, -2, 0, 1,100, 401233

  > Floating Point Numbers have decimal
    parts: -2.5 , 0.0, 98.6, 14.0

- There are other number types - they
  are variations on float and integer

```
>>> xx = 1
>>> type (xx)
<type 'int'>
>>> temp = 98.6
>>> type(temp)
<type 'float'>
>>> type(1)
<type 'int'>
>>> type(1.0)
<type 'float'>
>>>
```

Type Conversions

- When you put an integer and
  floating point in an expression,
  the integer is implicitly
  converted to a float

- You can control this with the
  built-in functions int() and
  float()

```
>>> print float(99) / 100
0.99
>>> i = 42
>>> type(i)
<type 'int'>
>>> f = float(i)
>>> print f
42.0
>>> type(f)
<type 'float'>
>>> print 1 + 2 * float(3) / 4 - 5
-2.5
>>>
```

String Conversions

Microsoft

- You can also use int() and float() to convert between strings and integers

- You will get an error if the string does not contain numeric characters

```
>>> sval = '123'
>>> type(sval)
<type 'str'>
>>> print sval + 1
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: cannot concatenate 'str'
and 'int'
>>> ival = int(sval)
>>> type(ival)
<type 'int'>
>>> print ival + 1
124
>>> nsv = 'hello bob'
>>> niv = int(nsv)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: invalid literal for int()
```

User Input

Microsoft

- We can instruct Python to pause and read data from the user using the raw_input() function

- The raw_input() function returns a string

```
nam = raw_input('Who are you?')
print 'Welcome', nam
```

```
Who are you? DI-Team Member
Welcome DI-Team Member
```

12

Converting User Input

- If we want to read a number from the user, we must convert it from a string to a number using a type conversion function

- Later we will deal with bad input data

```
inp = raw_input('Europe floor?')
usf = int(inp) + 1
print 'US floor', usf
```

```
Europe floor? 0
US floor 1
```

Comments in Python

- Anything after a # is ignored by Python

- Why comment?
  > Describe what is going to happen in a sequence of code
  > Document who wrote the code or other ancillary information
  > Turn off a line of code - perhaps temporarily

Microsoft

```
# Get the name of the file and open it
name = raw_input('Enter file:')
handle = open(name, 'r')
text = handle.read()
words = text.split()

# Countword  frequency
counts =dict()
for word in words:
    counts[word] = counts.get(word,0) + 1

# Find the most common word
bigcount = None
bigword = None
for word,count in counts.items():
    if bigcount is None or count > bigcount:
        bigword = word
        bigcount = count

# All done
print bigword, bigcount
```

Microsoft

String Operations

- Some operators apply to strings

  > + implies "concatenation"

  > * implies "multiple concatenation"

- Python knows when it is dealing with a string or a number and behaves appropriately

```
>>> print 'abc' +'123'
abc123
>>>print 'Hi' *5
HiHiHiHiHi
>>>
```

Mnemonic Variable Names

- Since we programmers are given a choice in how we choose our variable names, there is a bit of "best practice"

- We name variables to help us remember what we intend to store in them ("mnemonic" = "memory aid")

- This can confuse beginning students because well-named variables often "sound" so good that they must be keywords

http://en.wikipedia.org/wiki/Mnemonic

```
x1q3z9ocd = 35.0
x1q3z9afd = 12.50
x1q3p9afd = x1q3z9ocd * x1q3z9afd
print x1q3p9afd
```
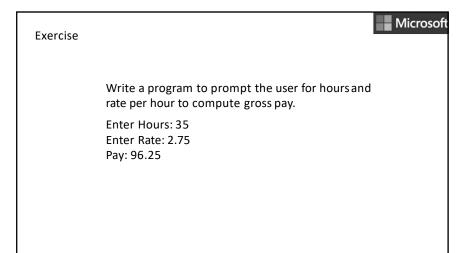

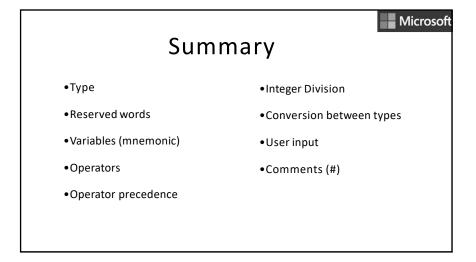

What is this bit of
code doing?

Slide 1 (left)

```
x1q3z9ocd = 35.0                              a = 35.0
x1q3z9afd = 12.50                             b = 12.50
x1q3p9afd = x1q3z9ocd * x1q3z9afd             c = a * b
print x1q3p9afd                               print c
```

What are these
bits of code doing?

Slide 2 (right)

```
x1q3z9ocd = 35.0                              a = 35.0
x1q3z9afd = 12.50                             b = 12.50
x1q3p9afd = x1q3z9ocd * x1q3z9afd             c = a * b
print x1q3p9afd                               print c
```

What are these
bits of code doing?

```
hours = 35.0
rate = 12.50
pay = hours * rate
print pay
```

Microsoft

Exercise

Write a program to prompt the user for hours and rate per hour to compute gross pay.

Enter Hours: 35
Enter Rate: 2.75
Pay: 96.25

Microsoft

Summary

- Type
- Reserved words
- Variables (mnemonic)
- Operators
- Operator precedence

- Integer Division
- Conversion between types
- User input
